

Updating unifiedcloudsensors.com — Instructions for Radek

2026-09-20 · Prepared by Evgeny

This is the workflow for making changes to **unifiedcloudsensors.com** (the corporate "about us" site) without needing to code or touch AWS directly. You chat with Claude Code, which does the actual editing, and everything ships through GitHub.

Short answer to "do I need a GitHub account": yes. You need your own GitHub account, and the project owner needs to add you as a collaborator on the repo (`utilcellsro/sensweight-web` — both `unifiedcloudsensors.com` and `sensweight.com` live in this one repo). That login is also what authorizes publishing — there's no separate AWS access to request.

One-time setup

1. **Install Claude Code** — ask Evgeny for the install steps for your machine.
2. **Get a GitHub account** if you don't have one, and ask Evgeny to add you as a collaborator on `utilcellsro/sensweight-web`.
3. **Authenticate** — run `gh auth login` once in a terminal and follow the prompts.
4. **Clone the repo** — ask Evgeny for the one-line command, or use GitHub Desktop if you'd rather use a visual tool.
5. **Open the project folder in Claude Code.**

You do **not** need Docker or any build tooling for this site — unlike `sensweight.com`, `unifiedcloudsensors.com` is a single self-contained HTML file, so there's no build step at all.

The everyday loop

1. `/unified-new-task` — start

Tell Claude what you want changed, in your own words — a wording change, a new Careers listing, a new Updates item, a team photo, anything. It sets up a clean branch for the change.

2. Just describe what you want, in chat

Talk to Claude like a developer sitting next to you. It edits

`unifiedcloudsensors/index_v6.html` directly — you don't touch any files yourself.

3. `/unified-local-deploy` — see it for yourself

No Docker, no localhost URL — just open `unifiedcloudsensors/index_v6.html` directly in your browser (double-click it) and refresh after each change. Everything previews correctly **except** actually submitting the Contact/Careers forms — those only work on the real deployed site.

4. `/unified-finish-task` — lock in the change

Claude shows a plain-English summary of what changed and asks for your explicit yes before merging into `main`. This still doesn't publish anything to the live site.

5. `/unified-deploy-live` — publish it

Runs the GitHub Action that publishes to the real live site at **unifiedcloudsensors.com**. Same "no AWS, everything through your GitHub login" model as step 1.

What you never need to worry about

- **AWS** — no account, no credentials. `/unified-deploy-live` handles it all through GitHub.
- **Breaking the live site** — your changes only exist on your own branch until `/unified-finish-task`, and only go live after `/unified-deploy-live`.
- **Merge conflicts** — every task gets its own branch, so parallel work with others stays separate until each is finished.

If something goes wrong

- `/unified-deploy-live` fails → Claude will show which step failed and a link to the details. Share that link with Evgeny if you're not sure what to do next.
- Anything that looks like an AWS/infrastructure problem (not just a content change) → flag it to Evgeny rather than trying to resolve it yourself; that layer is intentionally kept out of this workflow.
